Professor David E. Speyer
Acknowledgments

I want to thank my advisor Andrew Snowden. If he was concerned about his first student using string diagrams instead of conventional algebraic notation, he never showed it. He has also listened to all of my ideas over the past 3 years and provided invaluable feedback and guidance. Without his input, this thesis would probably not exist. He did a great job reading drafts and correcting my grammar. I also want to thank Philip Tosteson. We dreamed up many of the ideas in this thesis together. He has played a large part in shaping the way that I see mathematics. I cannot imagine what I would have done with my time in Ann Arbor if we didn’t hang out every day. John Wiltshire-Gordon taught me to be a mathematician. We spent a lot of time together during my first three years in Ann Arbor and he taught me about representation theory and category theory. Moreover, John first outlined the theorem in chapter 5 to me, I just filled in the details. John is also the person that got me interested in computing. Hopefully, one day, I will be as good at it as he is. Visiting Corey Jones and Scott Morrison in 2016 played a big role in my mathematical development. They taught me about tensor categories and how to compute inside them using string diagrams. Without them, this thesis would be very different and less exciting. I want to thank David, James and Thomas for sitting on my thesis committee. Anna and Hobie have been great roommates for the past two years. They have made my life so much easier and I would not have been able to do this without their moral support. My family, Philip, Kerry and Rebecca are the reason I am here. They taught me that there is nothing more important than understanding things. Moreover, they always listen when things go wrong and try to make things better. Thank you. I want to thank all of my friends in Ann Arbor. You know who you are. I have enjoyed playing Frisbee with all of you.

Introduction

This thesis consists of five chapters. The first is an introduction to tensor categories and the graphical calculus which we use to compute inside them. Chapters two through five each contain an independent result proved during my time at the University of Michigan.

**Chapter 1.** It has long been known to researchers in category theory and physics that computations internal to a tensor category can be expressed using string diagrams up to isotopy. This observation goes back to Penrose in [Pen71]. Moreover, they are an important part of the book [Pen05]. Here is an example of a string diagram:

In Chapter 1, we explore the string diagram calculus and define $6j$-symbols which are a coordinate representation of the associator in a tensor category. They will be important in later chapters.

In section 1.1, we describe the importance of braided tensor categories in topological quantum computing. In section 1.2 we introduce string diagrams in the context of $SL_2(\mathbb{C})$-representations. In section 1.3, we introduce the trivalent vertex string diagrams which can be defined inside any tensor category. These trivalent vertices are to tensor categories as bases are to vector spaces. We also define the $6j$-symbols, which are needed when computing with the trivalent vertex string diagrams. In section 1.4, we compute the symmetric and braided structures on the sub tensor category of $SL_2(\mathbb{C})$-representations generated by the first fundamental representation. In section 1.5, we define semi-normal forms. These
generalize Young’s semi-normal form for simple reflections in the symmetric group. In section 1.6, we explain the ribbon argument which allows us to compute the action of the double braid on the trivalent string diagrams.

Chapter 2. The $6j$-symbols contain a lot of information about their tensor category. Together with the fusion ring, they determine the tensor category upto equivalence. They are also useful from a computational perspective: many numbers which are of interest in low dimensional topology and quantum computing can be expressed in terms of $6j$-symbols. Despite this, we only know explicit $6j$-symbols in a small number of cases. In Chapter 2, we compute some new $6j$-symbols in the category of polynomial $\text{GL}(\infty)$-representations:

**Theorem 1.** Let $\lambda \subseteq \mu$ be partitions such that $\mu \setminus \lambda$ has two boxes $(a_1, b_1), (a_2, b_2)$ not contained in a single row or column. Then

$$
(j^\lambda_{\square \square})^{-1} = \begin{pmatrix}
1 + 1/d & -1 + 1/d \\
1 & 1
\end{pmatrix}
$$

where $d = |a_1 - a_2| + |b_1 - b_2|$ is the axial distance in the skew partition $\mu \setminus \lambda$.

A precise definition of the matrix $j$ can be found in section 1.3. The fundamental idea is that Young semi-normal form encodes a large number of $6j$-symbols. It is easy to compute explicit matrix representations of endomorphism algebras from $6j$-symbols. We demonstrate that one can recover $6j$-symbols from matrix representations.

Chapter 3. In this thesis, we use some of the tensor categorial machinery developed by the quantum algebra community to study algebraic objects which appear in representation stability. In [SS16], Sam and Snowden prove that the twisted commutative algebra $\text{Sym}$ is Morita equivalent to the horizontal strip category. Their proof relies on a lemma proved by Olver in [Olv87]. In Chapter 3, we give a self contained proof that replaces Olver’s lemma with information about the associator in the underlying category of polynomial $\text{GL}(\infty)$-representations. In fact, we prove a quantum analogue of the theorem. The classical version follows by letting the parameter converge to 1.

In section 3.1, we explain a mild generalization of classical Morita theory in which we replace objects with their presentations with respect to a family of projectives. In section 3.2, we study the tensor algebra generated by an object inside an arbitrary semi-simple tensor category. In section 3.3, we complete the proof that the quantum symmetric algebra is morita equivalent to the horizontal strip category.

Chapter 4. One of the central open problems in quantum algebra is to decide if the braid group representations coming from a braided tensor category are irreducible. This
problem is important in topological quantum computing. Modular tensor categories can be used to describe (2+1)-dimensional TQFTs. If the associated braid group representations are irreducible, then braiding gives us a universal set of quantum gates. In Chapter 4, we give a local condition for irreducibility, which appears to be new. Moreover, we give a simplified proof that skew representations of the symmetric group are irreducible for the affine action.

Chapter 5. Let $\mathbf{FI}$ be the category of finite sets with injections. Finitely generated representations of $\mathbf{FI}$ are Noetherian. This was proved independently by Church, Ellenberg and Farb in [CEF15] and by Snowden in [Sno13] and implies finiteness results for the cohomology of configuration spaces. Let $\mathbf{T}$ be the category whose objects are rooted trees and morphisms are order embeddings preserving the root. In Chapter 5, we prove that finitely generated representations of $\mathbf{T}$ are noetherian. The main ingredient in the proof is Kruskal’s tree theorem. It would be interesting to find a category which is Noetherian as a result of the Graph minor theorem.
Tensor categories are ubiquitous in modern mathematics. In [ML98], one of the first books on category theory, a whole chapter is devoted to them. In the 90s, it was discovered that tensor categories provide a unifying framework for many interesting invariants in low-dimensional topology, for example the Jones polynomial. More recently, the quantum algebra community has been using tensor categories to describe (2+1)-dimensional topological quantum field theories. The book [Wan10] gives an overview and explains applications to topological quantum computation.

The modern theory of tensor categories is explained in [EGNO15], which is rigorous and self-contained, but does not explain the string diagram language that researchers use to discover and communicate computations. The author was lucky enough to learn how to use string diagrams from Scott Morrison and Corey Jones during a three week visit to the Australian National University and many video chat conversations.

Above, we referred to the modern theory of tensor categories. This requires some explanation. Historically, people studied Hopf algebras instead of their categories of representations. This is analogous to studying vector spaces by first choosing a basis: One can prove everything needed, but the theory is neither elegant nor easy to digest. The modern approach is to take the tensor category as the central object. From this perspective, Hopf algebras are equivalent (modulo technical details) to tensor functors into vector spaces. Such functors are plentiful and not the only way to study tensor categories. Hopf algebras still play a central role in constructing tensor categories, but they should be thought of as a tool rather than the central object of interest.

This chapter is meant to be expository. We are not going to describe the theory of tensor categories in a formal way. A rigorous and modern introduction can be found in [EGNO15]. Instead, we demonstrate how to use string diagrams as a tool for understanding tensor categories. The ideal reader is someone who knows the definition of a tensor category, but is otherwise skeptical of the abstraction. At first, we focus on finite dimensional $SL_2(\mathbb{C})$-representations. Slowly, we transition from the $SL_2(\mathbb{C})$ case to the general case. There
is some overlap between this chapter and [CFS95], but we assume the reader understands the representation theory of $SL_2(\mathbb{C})$, and we do not explicitly compute the $6j$-symbols, although we explain what they are and why they are important.

1.1 A Physical Motivation for Braided Tensor Categories

In quantum theory, the state of a physical system is specified by a vector in a Hilbert space. Consider the following situation: We have $n$ particles in $\mathbb{R}^2$ and each particle has some internal structure. If we treat the position of the particles classically, then the state of our system is specified by a point in a unitary vector bundle $H \to E \to C_n(\mathbb{R}^2)$ where $C_n(\mathbb{R}^2)$ is the configuration space of $n$ distinct points in $\mathbb{R}^2$ and $H$ is a finite dimensional Hilbert space. To specify the dynamics, we need to lift paths in $C_n(\mathbb{R}^2)$ to paths in $E$. More precisely, we need a unitary connection on $E$. We call the system topological if the chosen connection is flat. This means that small perturbations of the particles do not change their internal state, or equivalently, the curvature tensor of our chosen connection vanishes. Since $\pi_1(C_n(\mathbb{R}^2))$ is the braid group $B_n$, a flat unitary connection on $E$ is specified by a unitary representation $B_n \rightarrow H$.

If we take two such topological systems $B_n \rightarrow H$, $B_m \rightarrow K$ and combine them, we take the tensor product of the internal state spaces $H \otimes K$, and expect this Hilbert space to carry an action of $B_{n+m}$ compatible with the $B_n \times B_m$ action. This is a strict condition on the braid group representations we want to consider.

We can construct compatible families of braid group representations in the following way: Let $X$ be a semi-simple braided tensor category and choose a distinguished object $X \in X$. Then we have a family of compatible braid group representations $B_n \rightarrow \text{End}(X^\otimes n)$. These families are the main object of study in this thesis. Moreover, if we work with unitary braided tensor categories, the braid group actions are unitary, so they specify unitary connections. The tensor category captures more than just compatibility between braid group representations. The maps between objects in the tensor category encode how the quantum state transforms when particles interact. This is explained in [BH10].

From the physical perspective, one of the fundamental questions we can ask about a braid group representation $B_n \rightarrow H$ is whether $\mathbb{C}[B_n] \rightarrow \text{End}(H)$ is surjective. If this is the case, we get every unitary transformation $U : H \rightarrow H$ from the braid group action. As explained in [NC00], this implies that we can build quantum computers using systems which are modeled as above. These are called topological quantum computers. In Chapter 4 we give a new criteria for the surjectivity of $\mathbb{C}[B_n] \rightarrow \text{End}(H)$ when $H$ comes from a semi-simple braided tensor category. If we want to express quantum gates in terms of the
braid group, we need explicit formulas for the braid group representations coming from a braided tensor category. These matrix representations are encoded in the $6j$-symbols which we define in this chapter.

### 1.2 Representations of $\text{SL}_2(\mathbb{C})$

In this section, we describe, using string diagrams, the category $\text{Rep}(\text{SL}_2(\mathbb{C}))$, whose objects are finite dimensional representations of $\text{SL}_2(\mathbb{C})$. We assume that the reader is already familiar with the representation theory of $\text{SL}_2(\mathbb{C})$.

**Definition 2.** The algebraic group $\text{SL}_2(\mathbb{C})$ is defined by

$$\text{SL}_2(\mathbb{C}) = \left\{ \begin{pmatrix} a & b \\ c & d \end{pmatrix} : a, b, c, d \in \mathbb{C}, \quad ad - bc = 1 \right\}.$$ 

The standard representation is $V = \mathbb{C}^2 = \mathbb{C} \{e_1, e_2\}$ and $\text{SL}_2(\mathbb{C})$ acts via left multiplication.

**Theorem 3.** *Finite dimensional representations of $\text{SL}_2(\mathbb{C})$ are semi-simple. The irreducible representations are*

$$V_0 = \text{Sym}^0(V) \quad V_1 = \text{Sym}^1(V) \quad V_2 = \text{Sym}^2(V) \quad V_3 = \text{Sym}^3(V) \quad \cdots$$

A proof of Theorem 3 can be found in [Ser01].

**Definition 4.** If $W$ and $X$ are representations of $\text{SL}_2(\mathbb{C})$, then so is $W \otimes X$. The group action is defined by $g \cdot (w \otimes x) = gw \otimes gx$ on rank 1 tensors and extends linearly to the entire tensor product. The tensor flip $W \otimes X \to X \otimes W$ defined by $w \otimes x \mapsto x \otimes w$ intertwines the $\text{SL}_2(\mathbb{C})$ action. We encapsulate these facts by saying that the category of $\text{SL}_2(\mathbb{C})$-representations is a *symmetric tensor category*. For a precise definition, see [EGNO15] or [ML98].

Recall that the character of $V_n$ relative to the torus

$$\left\{ \begin{pmatrix} t & 0 \\ 0 & t^{-1} \end{pmatrix} \right\} \subseteq \text{SL}_2(\mathbb{C})$$

is the polynomial $c_n = t^n + t^{n-2} + \cdots + t^2 - t^n$. Since we have $c_1^2 = c_0 + c_2$, it follows that

$$V^\otimes 2 \cong \mathbb{C} \oplus V_2.$$
**Definition 5.** In quantum algebra, we describe maps in a tensor category using **string diagrams**. The string diagram for the inclusion $C \to V \otimes V$ is

![Diagram](attachment:image.png)

We can extract information from the string diagram as follows: If we read the dots along the top edge from left to right, we get the sequence $(1, 1)$. This tells us that the codomain is $V_1^\otimes 2$. If we read the dots along the bottom edge from left to right, we get the empty sequence $(\cdot)$. This tells us the domain is $C$. Therefore the string diagram specifies a morphism $C \to V^\otimes 2$. There is a 1-dimensional space of such morphisms, so we need to choose a specific one. We take

$$
\begin{pmatrix}
0 \\
1 \\
-i \\
0
\end{pmatrix}
$$

where the basis on $V_1^\otimes 2$ is $\{e_1 \otimes e_1, e_1 \otimes e_2, e_2 \otimes e_1, e_2 \otimes e_2\}$. It is routine to check that this map is $\text{SL}_2(\mathbb{C})$-equivariant. The string diagram for the inclusion $\text{Sym}^2(V) = V_2 \hookrightarrow V \otimes V$ is

![Diagram](attachment:image.png)

The sequence along the top edge is $(1, 1)$, indicating that the domain is $V_1 \otimes V_1$. The sequence along the bottom edge is $(2)$, indicating that the domain is $V_2$. Again, there is a
1-dimensional space of such morphisms, and we make the following choice:

\[
\begin{pmatrix}
1 & 0 & 0 \\
0 & 1/2 & 0 \\
0 & 1/2 & 1 \\
0 & 0 & 1
\end{pmatrix}
\]

We call the box the **boundary** of the string diagram. We call the dots on the boundary the **fixed points** of the string diagram. It is common to draw string diagrams without their boundary or fixed points. Often the fixed point labels are also omitted if they can be inferred from the context. Because we are optimists, we read from the bottom of the page to the top. We denote the pairing \( V \otimes V \to \mathbb{C} \) with the following string diagram:

\[
\begin{pmatrix}
1 & 1 \\
1 & 1
\end{pmatrix}
\]

Again, there is a 1-dimensional space of such morphisms, so we take

\[
\begin{pmatrix}
0 & i & -i & 0
\end{pmatrix}
\]

as our specific pairing. Another important equivariant map \( V \to V \) is the identity map. The corresponding string diagram is

\[
\begin{pmatrix}
1
\end{pmatrix}
\]

**Definition 6.** In a tensor category we can compose and tensor morphisms. In terms of
In this diagram we have omitted the boundary box, fixed points and string labels as explained in Definition 5. It is important to note that two string diagrams can be composed only when the fixed points and string labels match in the middle. This is equivalent to saying that $g \circ f$ is defined only when the domain of $g$ equals the codomain of $f$. For string diagrams, tensor product is horizontal stacking:

Unlike composition, we do not need to match fixed points and string labels for the tensor product.

**Example 7.** Let us look at some explicit computations in $\text{Rep}(\text{SL}_2(\mathbb{C}))$:

$$
\begin{pmatrix}
0 & i & -i & 0 \\
0 & i & -i & 0
\end{pmatrix}^T = -2
$$
The last equation is interesting because it implies that

\[
\begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & i & -i & 0 \\
0 & -i & i & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix}
= \begin{pmatrix}
0 & 0 & 0 & 0 \\
0 & -1 & 1 & 0 \\
0 & 1 & -1 & 0 \\
0 & 0 & 0 & 0
\end{pmatrix}
\]

which is the tensor flip \( V \otimes V \rightarrow V \otimes V \). We introduce the following notation for the tensor flip:

\[
\begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 0 & 1
\end{pmatrix}
\]

Addition of string diagrams corresponds to addition of linear maps. Note that we can only add string diagrams when the fixed points and fixed point labels match. Both compo-
sition and tensor product of string diagrams are bilinear. Consider the following equation:

\[
\begin{pmatrix}
1 & 0 \\
0 & 1
\end{pmatrix}
\]

The mirrored computation gives us

\[
\begin{pmatrix}
0 & i & 0 & -i & 0 & 0 & 0 \\
0 & 0 & 0 & i & 0 & 0 & -i
\end{pmatrix}
\]

which seems to suggest that the equivariant map represented by a string diagram is an isotopy invariant. Here is another example:

\[
\begin{pmatrix}
0 & i & 0 & 0 & -i & 0 & 0 & 0 \\
0 & 0 & 0 & i & 0 & 0 & -i & 0
\end{pmatrix}
\]

This is a special case of the following:

**Theorem 8** (informal). *Morphisms in a *\(\ast\) tensor category, where *\(\ast\) is any of the usual adjectives (symmetric, braided, pivotal, ribbon), are described by string diagrams modulo isotopy relative to their boundary fixed points.*

In [JS91], Street and Joyal give a rigorous proof in some special cases. A more complete but informal discussion of Theorem 8 can be found in [Sel11]. Morally, Theorem 8 is a special case of the cobordism hypothesis which states that the \((\infty,n)\)-category of cobordisms is the free symmetric monoidal \((\infty,n)\)-category with duals generated by a single object. Details can be found in [Fre13]; we will not be pursing that idea further. If our tensor category is realized as representations over a Hopf algebra, we can easily convert any string diagram equation into a matrix tensor equation which can be checked by hand.
or in a computer. For example, Theorem 8 implies that

\[ \begin{array}{c}
\includegraphics[scale=0.5]{example_diagram}
\end{array} \]

and it is easy to check that both sides are equal to the matrix

\[
\begin{pmatrix}
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & -1 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & 0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 & -1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & -1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 0
\end{pmatrix}
\]

This is a well known relation in the Temperly–Lieb algebra \( \text{End}_{\text{SL}_2}(V^\otimes 3) \).

As an application of the string diagrams we have seen so far, let us fully describe \( \text{hom}_{\text{SL}_2}(V^\otimes m, V^\otimes n) \). Since the first fundamental representation of \( \text{SL}_2(\mathbb{C}) \) is self dual, we have an isomorphism \( \text{hom}_{\text{SL}_2}(V^\otimes m, V^\otimes n) \to \text{hom}_{\text{SL}_2}(V^\otimes (m+n), \mathbb{C}) \) defined by

\[ f \mapsto f \]

Therefore, it suffices to describe the invariant spaces \( \text{hom}_{\text{SL}_2}(V^\otimes n, \mathbb{C}) \) in terms of the string diagrams. Using characters, we can check that

\[
\dim \text{hom}_{\text{SL}_2}(\mathbb{C}, V^\otimes n) = \begin{cases} 
0 & n \text{ odd} \\
C_d & n = 2d
\end{cases}
\]

where \( C_d \) is the \( d \)th Catalan number. It is well known that there are \( C_d \) string diagrams with no crossings and \( 2d \) fixed points on the bottom boundary. These string diagrams are a basis.
for $\text{hom}_{\text{SL}_2}(\mathbb{C}, V^\otimes 2^d)$. For example, when $d = 3$, the following diagrams form a basis:

![Diagrams](image)

### 1.3 Trivalent vertex diagrams and the 6$j$-symbols

In Section 1.2, we used our understanding of $\text{SL}_2(\mathbb{C})$ to produce string diagrams. It turns out that we can produce a general set of **trivalent vertex string diagrams** in any semi-simple tensor category and they are the focus of this section.

**Definition 9.** Let $X$ be a semi-simple tensor category. Index the simple objects with a set $\Lambda$. Choose a basis for each $X(\mu, \lambda \otimes \nu)$ denoted by

![Basis Diagram](image)

and let

![Dual Basis Diagram](image)

be the dual basis of $X(\lambda \otimes \nu, \mu)$. We call these diagrams **trivalent vertices**. It is important to notice that trivalent vertices are not canonically defined.

**Definition 10.** Pick a distinguished simple object $X \in X$. The **fusion graph** of $X$ has vertices $\Lambda$ and the edges from $\lambda$ to $\mu$ are the distinguished basis vectors in $X(\mu, \lambda \otimes X)$.
**Proposition 11.** Fix $\lambda \in \Lambda$. Then $X(\lambda, X^{\otimes n})$ has dimension the number of paths from the tensor unit to $\lambda$ in the fusion graph for $X$ of length $n$. Moreover, an explicit basis is given by string diagrams of the form

In this diagram, each $f_i$ is a trivalent vertex of the form

we call such string diagrams **trivalent basis vectors**

**Proof.** Decompose $X^{\otimes n}$ using the fusion graph for $X$. $\square$

**Definition 12.** If $X$ is a semi-simple tensor category over $\mathbb{C}$ with finite dimensional morphism spaces, the Artin-Wedderburn Theorem implies that $\text{End}(X^{\otimes n})$ is a product of matrix algebras. Proposition 11 implies that in the trivalent basis, the matrix units in $\text{End}(X^{\otimes n})$ look like
Equivalently, the irreducible representations of $\text{End}(X^{\otimes n})$ are parameterized by the simple objects in $X$ which have a length $n$ path from the tensor unit in the fusion graph for $X$. The string diagrams defined in Proposition 11 form a basis for the corresponding representation.

**Definition 13.** Fix $\lambda_1, \lambda_2, \lambda_3, \mu \in \Lambda$. Then we have two bases for $X(\mu, \lambda_1 \otimes \lambda_2 \otimes \lambda_3)$:

\[
\begin{align*}
\lambda_1 & \quad \lambda_2 & \quad \lambda_3 \\
\mu & \quad \lambda_1 & \quad \lambda_2 \\
\lambda_2 & \quad \alpha & \quad \lambda_3 \\
\lambda_3 & \quad \lambda_2 & \quad \lambda_1 \\
\mu & \quad \beta & \quad f_1 \\
e_1 & \quad \alpha & \quad e_2 \\
e_2 & \quad \lambda_3 & \\
\lambda_2 & \quad \beta & \quad f_1 \\
\beta & \quad \lambda_2 & \\
\mu & \quad \lambda_3 & \\
f_1 & \quad \lambda_1 & \\
f_2 & \quad \lambda_3 & \\
\mu & \quad \lambda_3 & 
\end{align*}
\]

The $6j$-symbols are the entries in the change of basis matrix $(f^\mu_{\lambda_1, \lambda_2, \lambda_3} f_{e_1, e_2})$. In other words, they are a coordinate representation of the associator. They must satisfy some algebraic relations which correspond to the pentagon axiom and the unit axiom. From the $6j$-symbols and the Grothendieck ring, we can recover the tensor category. Therefore, the $6j$-symbols are coordinates on the moduli stack of semi-simple tensor categories with a fixed Grothendieck ring.

**Example 14.** Let $G$ be a finite group. Consider a semi-simple tensor category over $\mathbb{C}$ with Grothendieck ring $\mathbb{N}[G]$. We write $V_g$ for the simple object corresponding to $V_g$. On objects, the tensor product is given by $V_g \otimes V_h = V_{gh}$. In order to fully specify the tensor category, we need to choose an associator:

$$V_{ghi} = (V_g \otimes V_h) \otimes V_i \cong V_g \otimes (V_h \otimes V_i) = V_{ghi}$$

Any such map is multiplication by a constant, therefore the associator is a function $a : G^3 \to$
\( \mathbb{C} \). The associator must satisfy the pentagon relation:

\[
\begin{array}{c}
((gh)i)j \\
(g(hi))j \\
g(hi)j \\
\end{array}
\]

which implies that

\[
a(g,h,i)a(g,h,ij)^{-1}a(g,hi,j)a(gh,i,j)^{-1}a(h,i,j) = 1.
\]

Therefore the associator \( a \) defines a cohomology class in \( H^3(G, \mathbb{C}^\times) \). Moreover, two associators give equivalent tensor categories if and only if their quotient is a coboundary. We can also construct tensor equivalences using automorphisms of \( G \). Since conjugation acts trivially on group cohomology, the moduli space of semi-simple tensor categories with Grothendieck ring \( \mathbb{N}[G] \) is \( H^3(G, \mathbb{C}^\times)/\text{Out}(G) \).

**Example 15.** Let \( X = \text{Rep}(\text{SL}_2(\mathbb{C})) \) be the category of finite dimensional \( \text{SL}_2(\mathbb{C}) \)-representations and \( X = V \) the first fundamental representation. We can check using characters that

\[
\text{Sym}^n(V) \otimes V = \text{Sym}^{n-1}(V) \oplus \text{Sym}^{n+1}(V).
\]

Therefore the fusion graph for \( V \) looks like

\[
\begin{array}{c}
\cdots
\end{array}
\]

The endomorphism algebra \( \text{End}(V^{\otimes n}) \) is called the Temperley-Leib algebra, and we de-
scribed it in terms of string diagrams in section 1.2. In this example, we can take

\[
\begin{array}{c}
1 & 1 \\
\downarrow & \\
0 & \downarrow \\
\end{array}
\end{array}
= \begin{array}{c}
1 \\
\end{array}
\]

which implies that

\[
\begin{array}{c}
1 & 1 \\
\downarrow & \\
0 & \downarrow \\
\end{array}
= -2 \begin{array}{c}
1 \\
\end{array}
\end{array}
\]

\[
\begin{array}{c}
1 & 1 \\
\downarrow & \\
0 & \downarrow \\
\end{array}
= 0
\]

If we have explicit formulas for the 6j-symbols, then evaluating expressions like

\[
\begin{array}{c}
2 & 3 \\
\downarrow & \\
2 & \downarrow \\
\end{array}
\end{array}
\]

into the tree basis is reduced to an explicit computation: associate then evaluate then associate back. Therefore, if we have explicit formulas for the 6j-symbols, we get explicit matrix representations of the endomorphism algebras End(X^⊗n). In the SL₂(ℂ) case, explicit formulas for the 6j-symbols are computed in [CFS95].

**Example 16.** Let \( X = \text{Rep}(G_2) \) be the category of finite dimensional \( G_2 \)-representations and \( X = V \) be the first fundamental representation. The dominant integral weight lattice for \( G_2 \) looks like:
In the fusion graph, every vertex that is not on the solid vertical line has a self loop. Let $d$ be the shortest distance between two different dominant integral weights. For every vertex, there is a directed edge to all vertices which are distance $d$ away. For a generic vertex, there are seven outgoing edges, one of them a self loop.

1.4 Transitioning into the Braided World

Define $\mathbf{TL}(\delta)$ to be the tensor category generated by

\[
\begin{array}{c}
\text{\begin{tabular}{c}
\end{tabular}}
\end{array}
\]

with the following relation:

\[
= \delta
\]

This is the free tensor category generated by a self dual object $V$ such that the composition $k \rightarrow V \otimes V \rightarrow k$ is multiplication by the scalar $\delta$. The category $\mathbf{TL}(\delta)$ is equivalent to the sub-tensor category of $\text{SL}_2(\mathbb{C})$-representations generated by the first fundamental representation. Moreover, if we take the idempotent completion of $\mathbf{TL}(\delta)$, we recover the category of all finite dimensional $\text{SL}_2(\mathbb{C})$-representations. It is natural to ask how many different symmetric structures exist on $\mathbf{TL}(\delta)$.
**Proposition 17.** Up to negation, the only symmetric structure on $\text{TL}(\delta)$ is

\[
\begin{array}{c}
\begin{array}{c}
\times \\
\end{array}
\end{array}
= \begin{array}{c}
\begin{array}{c}
\end{array}
\end{array} + \begin{array}{c}
\begin{array}{c}
\end{array}
\end{array}
\]

**Proof.** The endomorphism algebra of the second tensor power in $\text{TL}(\delta)$ is two dimensional. This implies the general symmetric structure looks like

\[
\begin{array}{c}
\begin{array}{c}
\times \\
\end{array}
= a \\
\end{array} + b
\]

Define the pivoting map by the formula

\[
\begin{array}{c}
\begin{array}{c}
\text{f} \\
\end{array}
\end{array} \mapsto \begin{array}{c}
\begin{array}{c}
\text{f} \\
\end{array}
\end{array} = \begin{array}{c}
\begin{array}{c}
\text{f} \\
\end{array}
\end{array}
\]

Up to isotopy, the pivoting map rotates the string diagrams by 90 degrees. We can build the pivoting map out of cups and caps using composition and tensor product. Therefore, applying the pivoting map to an equation in the tensor category gives a new equation. If we apply the pivoting map to the general symmetric structure and equate coefficients, then we get $a = b$. If we square the tensor flip and take coefficients of the identity, then we get $a^2 = 1$ which implies $a = \pm 1$. Therefore, up to negation, there is at most one symmetric monoidal structure on $\text{TL}(\delta)$.

In particular, this proves that the category of finite dimensional $\text{SL}_2(\mathbb{C})$-representations is rigid as a symmetric monoidal category.

Now let us think about braided monoidal structures on $\text{TL}(\delta)$. In a symmetric monoidal category, the tensor flip behaves like a generator in the symmetric group. In a braided monoidal category, the tensor flip behaves like a generator in the braid group.
Proposition 18. On the tensor category $\text{TL}(-a^2 - 1/a^2)$, a braiding must be of the form

\[
\begin{array}{c}
\text{\includegraphics{diagram1}}
\\= a
\\+ \frac{1}{a}
\end{array}
\]

Proof. The general braiding looks like

\[
\begin{array}{c}
\text{\includegraphics{diagram2}}
\\= a
\\+ b
\end{array}
\]

If we apply the pivot map to this equation, we get

\[
\begin{array}{c}
\text{\includegraphics{diagram3}}
\\= b
\\+ a
\end{array}
\]

If we compose these string diagrams, we get the equations $ab = 1$ and $a^2 + b^2 = ab\delta$ which implies that $b = 1/a$ and $\delta = -a^2 - 1/a^2$. \hfill \Box

When $a$ is generic, this braided tensor category is well known as the type 1 representations of the quantum group $U_a(\mathfrak{sl}_2)$.

1.5 Semi-Normal forms

For most tensor categories of interest, the $6j$-symbols with respect to any trivalent vertices are out of reach. If we care about explicit representations of endomorphism algebras, then we don’t need to compute a full set of $6j$-symbols.

Definition 19. Let $X$ be a semi-simple tensor category with distinguished object $X$. If
\( \sigma \in \text{End}(X^{\otimes 2}) \) then we have

\[ \lambda \quad \sigma \quad \mu \]

\[ = \sum_{f,g} m_{fg,ab}(\sigma) \]

We call the matrix \( m(\sigma) \) a **semi-normal form** for \( \sigma \).

**Example 20.** Consider the multiplicity space \( \text{hom}_{\text{SL}_2(\mathbb{C})}(V_1, V_1^{\otimes 3}) \). It has basis

\[
\begin{bmatrix}
1 & 1 & 1 & 1 & 1 & 1 \\
0 & 0 & 1 & 1 & 0 & 1 \\
1 & 1 & 1 & 0 & 0 & 1 \\
\end{bmatrix}
\]

To compute the semi-normal form of the tensor flip in this case, we need to choose matrix representations for each trivalent vertex:

\[
\begin{bmatrix}
1 \\
0 \\
\end{bmatrix}
= \begin{pmatrix} 0 \\ i \\ -i \\ 0 \end{pmatrix}
\]

\[
\begin{bmatrix}
0 \\
1 \\
1 \\
\end{bmatrix}
= \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix}
\]
The last matrix is somewhat mysterious and we leave its computation as an exercise. From these equations, we get

These matrices are a basis for the multiplicity space $\text{hom}_{\text{SL}_2(\mathbb{C})}(V_1, V_1^\otimes 3)$. We choose a
matrix representation for the tensor flip:

\[
\begin{bmatrix}
1 & 0 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1 \\
0 & 0 & 0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & 0 & 0 & 1
\end{bmatrix}
\]

From this, we compute the semi-normal form:

\[
\begin{pmatrix}
1/2 & 3i/4 \\
-i & -1/2
\end{pmatrix}
\]

Example 21. The **Iwahori-Hecke algebra**, denoted by \( H_m \), is the algebra generated over \( \mathbb{C}(a) \) by \( 1, g_1, \ldots, g_{m-1} \) subject to the relations

\[
g_i g_{i+1} g_i = g_{i+1} g_i g_{i+1}
\]

\[
g_i g_j = g_j g_i \quad \text{if} \quad |i - j| \geq 2
\]

\[
g_i^2 = (a - a^{-1}) g_i + 1.
\]

We define the category \( H \) which has objects the natural numbers and morphisms

\[
H(m,n) = \begin{cases} 
H_m & m = n \\
0 & \text{otherwise}.
\end{cases}
\]

The inclusion \( H_m \otimes H_n \to H_{m+n} \) defined by \( g_i \otimes g_j \mapsto g_i g_{m+j} \) equips \( H \) with a tensor structure. We define \( \mathcal{H} \subseteq [H^{\text{op}}, \text{Vec}] \) to be the idempotent completion of \( H \). The monoidal structure on \( H \) extends to \( \mathcal{H} \) via Day convolution. Morally, the category \( \mathcal{H} \) can be described as finite dimensional type 1 representations of the quantum group \( U_a(g_{\ell}) \). The Grothendieck ring for \( \mathcal{H} \) has basis given by partitions and multiplication given by the Littlewood-Richardson rule. A special case of the Littlewood-Richardson rule is the Pieri rule:

\[
\lambda \otimes \square = \sum_{\lambda \subset \mu + \nu + 1} \mu
\]
This implies that the fusion graph for □ is Young’s graph:

Paths in the Young graph are in bijection with standard partition fillings. It follows that the trivalent basis vectors

\[ e_{m+1} e_{m+2} e_{m+3} e_{m+4} \]

are in bijection (up to scaling) with standard skew tableaux of shape \( \mu \setminus \lambda \). We abuse notation and identify these tree basis vectors with the corresponding standard skew tableaux. In [LR97], Ram and Leduc computed semi-normal forms for the Iwahori-Hecke algebras. More precisely, suppose that \( \lambda \subseteq \mu \vdash n + 2 \) are partitions such that \( \mu \setminus \lambda \) is not contained in a single row or column. Then there are exactly two partitions which satisfy \( \lambda \subseteq \nu \subseteq \mu \). Call them \( \nu \) and \( \nu' \). The multiplicity space \( \mathcal{H}(\mu, \lambda \otimes \square \otimes \square) \) is 2-dimensional with basis

\[ \lambda, \nu, \nu', \mu \]
We have
\[ m(g_1) = \begin{pmatrix} a^d/[d] & [d-1][d+1]/[d]^2 \\ 1 & a^{-d}/[-d] \end{pmatrix} \]
where
\[ [n] = \frac{a^n - a^{-n}}{a - a^{-1}} \]
and \( d = d_1 + d_2 \) is the axial distance in \( \mu \setminus \lambda \):

More formally, if \( \mu \setminus \lambda \) contains the boxes \((a_1, b_1), (a_2, b_2)\), then the axial distance is defined by \( d = |a_1 - a_2| + |b_1 - b_2| \). These formulas are quantum analogues of the well known Young semi-normal form for the representation theory of the symmetric group [JK81]. Indeed, when \( a \to 1 \), they recover the classical Young semi-normal formulas.

1.6 The Ribbon Argument

Suppose that \( X \) is a braided tensor category and each object has a dual. Then for each simple object \( \lambda \), we have

\[ \lambda \]
\[ \Theta = \theta_{\lambda} \]
\[ \lambda \]
where $\theta_\lambda$ is a constant. If $\lambda^*$ is the dual of $\lambda$, $p : \lambda \otimes \lambda^* \to \mathbb{C}$ is the pairing, $c : \mathbb{C} \to \lambda \otimes \lambda^*$ is the co-pairing and $\sigma : \lambda \otimes \lambda \to \lambda \otimes \lambda$ is the braiding, then

\[
\lambda = (\text{id} \otimes p)(\sigma \otimes \text{id})(\text{id} \otimes c)
\]

The constants $\theta_\lambda$ are always known explicitly in practice. For example, in the quantum group case, we have $\theta_\lambda = a^{-\langle \lambda, \lambda + 2\rho \rangle}$ where $\rho$ is the half sum of positive roots. We have the following beautiful equation:

\[
\begin{align*}
\begin{array}{c}
\lambda \quad \lambda \\
\downarrow \quad \downarrow \\
\nu \quad \theta_\lambda \theta_\nu \\
\mu \quad \mu
\end{array}
\end{align*}
\]

This implies that

\[
\begin{align*}
\begin{array}{c}
\lambda \quad \lambda \\
\downarrow \quad \downarrow \\
\nu \quad \theta_\lambda \theta_\nu \\
\mu \quad \mu
\end{array}
= \frac{1}{\theta_\lambda \theta_\nu}
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
\lambda \quad \lambda \\
\downarrow \quad \downarrow \\
\nu \quad \theta_\lambda \theta_\nu \\
\mu \quad \mu
\end{array}
= \frac{1}{\theta_\lambda \theta_\nu}
\end{align*}
\]
In words, the trivalent basis vectors are eigenvectors for the double braid and we can explicitly compute the eigenvalues. This is called the ribbon argument and will be important for motivation in Chapter 4. There is one subtle point worth mentioning. Although we can perform the ribbon argument in any braided tensor category with duals, there are several slight variants of the argument which might produce different scalars $\theta'_\lambda$. The root of this issue is the distinction between left and right traces, and it goes away when left and right traces are equal:

For this reason, a braided tensor category with duals where left and right traces agree is called a **ribbon tensor category**.
CHAPTER 2

Semi-Normal Forms and 6j Symbols

A semi-simple tensor category is determined up to equivalence by its Grothendieck ring and its 6j-symbols with respect to a set of tree basis vectors. The 6j-symbols are the coordinate representation of the associator. Despite their importance, we only know explicit formulas for 6j-symbols in a few special cases. In the $\text{SL}_2(\mathbb{C})$ and $U_a(\mathfrak{sl}_2)$ cases, explicit formulas for the 6j-symbols are computed in [CFS95]. As far as the author is aware, the only other case where explicit 6j-symbols are known is $G$-graded vector spaces for $G$ a finite group.

In this chapter, we compute a large number of 6j-symbols inside the tensor category $\mathcal{H}$ consisting of polynomial type 1 representations of $U_a(\mathfrak{gl}_\infty)$. This category was defined in Example 21.

Suppose that $\lambda \subseteq \mu + n + 2$ are partitions such that $\mu \setminus \lambda$ is not contained in a single row or column. There are exactly two partitions which satisfy $\lambda \subseteq \nu \subseteq \mu$. Call then $\nu$ and $\nu'$. The multiplicity space $\mathcal{H}(\lambda \otimes \square \otimes \square, \mu)$ is 2-dimensional and we have the following two bases:

$$
\begin{align*}
\begin{cases}
\lambda \\
\nu \\
\mu
\end{cases},
\begin{cases}
\lambda \\
\nu' \\
\mu
\end{cases}
\end{align*}
\quad
\begin{align*}
\begin{cases}
\lambda \\
\square \\
\mu
\end{cases},
\begin{cases}
\lambda \\
\square \\
\mu
\end{cases}
\end{align*}
$$

The 6j-symbols are the entries of the matrix relating these two bases.

**Proposition 22.** Let $\lambda \subseteq \mu$ be partitions such that $\mu \setminus \lambda$ has two boxes not contained in a single row or column. Then

$$
(j_{\mu}^{\lambda, \square, \square})^{-1} = \begin{pmatrix}
\frac{a^{2d+2} - 1}{a(a^2d - 1)} & \frac{a^2 - a^{2d}}{a(a^2d - 1)} \\
1 & 1
\end{pmatrix}
$$
where $d$ is the axial distance in the skew partition $\mu \setminus \lambda$.

Proof. Identify $\square$ with projection onto the corresponding isotypic component in $H_2$. We have

$$\square = \frac{1}{1 + a^2} (e + ag_1).$$

where $g_1$ is the simple reflection. This formula generalizes the invariant symmetrizer from the symmetric group. It follows that

$$m(\square) = \frac{1}{1 + a^2} (1 + am(g_1)) = \begin{pmatrix}
a^{2d+2} - 1 & \frac{a^{2d} - a^2}{(a^2 + 1)(a^{2d} - 1)} \\
\frac{a}{a^2 + 1} & \frac{a^{2d} - a^2}{(a^2 + 1)(a^{2d} - 1)}
\end{pmatrix}$$

where $m$, defined in section 1.5, takes an algebra element to its semi-normal form matrix. On the left basis, $\square$ acts via $m(\square)$. On the right basis, $\square$ projects onto the first basis vector and kills the second basis vector. Therefore the basis vectors on the right are the $0$ and $1$ eigenvectors respectively for the matrix $m(\square)$. Computing these eigenvectors in the left basis proves the proposition.

If we take the limit as $a \to 1$ then we get the matrix

$$\begin{pmatrix}1 + 1/d & -1 + 1/d \\ 1 & 1\end{pmatrix}.$$}

This gives the $6j$-symbols in the category of polynomial $GL(\infty)$-representations. More generally, the same trick will work whenever $X \otimes X$ is multiplicity free and $\dim C(\mu, \lambda \otimes X \otimes X)$ equals the number of isotypic components in $X \otimes X$. Despite the simple proof, Proposition 22 shows us that we can extract $6j$-symbols from semi-normal forms. Therefore, computing semi-normal forms is as hard as computing $6j$-symbols.
CHAPTER 3

Minimal Model for the Quantum Symmetric Algebra

Let $S$ be the category of polynomial GL($\infty$)-representations studied by Sam and Snowden in [SS16]. This category contains the algebra $\text{Sym} = \mathbb{C}[x_1, x_2, \ldots]$ which is Morita equivalent to $\text{FI}$, the category of finite sets with injections. A proof can be found in [SS17]. In Section 3 of [SS16], Sam and Snowden prove that $\text{Sym}$ is Morita equivalent to $\text{HS}$, the category whose objects are partitions and whose morphisms are defined by

$$\text{HS}(\lambda, \mu) = \begin{cases} \mathbb{C}\{\mu \setminus \lambda\} & \lambda \subseteq \mu, \mu \setminus \lambda \in \text{HS} \\ 0 & \text{otherwise} \end{cases}$$

Composition is defined as follows: Assume that $\mu \setminus \lambda$ and $\nu \setminus \mu$ are horizontal strips. If $\nu \setminus \lambda$ is a horizontal strip, then

$$(\nu \setminus \mu)(\mu \setminus \lambda) = \nu \setminus \lambda.$$ 

If $\nu \setminus \lambda$ is not a horizontal strip, then the composition is zero. Now let $\mathcal{H}$ be the category of polynomial type 1 representations of $U_a(gl_\infty)$ defined in Example 21. Inside $\mathcal{H}$, we have the quantum symmetric algebra $Q\text{Sym}$. In this chapter, we prove the following:

**Theorem 23.** The quantum symmetric algebra $Q\text{Sym}$ is Morita equivalent to $\text{HS}$ for generic $a$.

Theorem 23 implies that many of the results in [SS16] which hold for $\text{Sym}$ are also true for $Q\text{Sym}$.

3.1 Morita Theory

In this section, we prove a very mild generalization of classical Morita theory. In classical Morita theory, we replace an object with its presentation with respect to a single projective.
We are going to replace an object with its presentation with respect to a family of projectives. For the remainder of this section, $X$ is an abelian category enriched over $\text{Vec}_k$, closed under colimits, $D$ is a category enriched over $\text{Vec}_k$ and $D^{\text{op}} \to X$ is a functor.

**Theorem 24.** If $X$ has enough projectives, then $X$ is equivalent to the category of representations of $D$ where $D^{\text{op}}$ is a full subcategory of $X$ whose objects are compact, projective and generate $X$.

We can prove this in a very clean way using coends. They can be motivated as follows: Suppose that $A$ is a $k$-algebra, $M$ is a left $A$-module and $N$ is a right $A$-module. Then we can form the tensor product $M \otimes_A N$ which is a vector space. It is built by taking the tensor product $M \otimes_k N$ and quotienting by the relations

$$am \otimes n = m \otimes na.$$  

We can generalize the second step in the following way. Suppose that $F : D \otimes_k D^{\text{op}} \to \text{Vec}_k$ is a bifunctor. Then we can form the vector space

$$\int^{d \in D} F = \bigoplus_{d \in D} F(d,d) / f v = v f \quad v \in F(d,d'), f : d' \to d.$$ 

This vector space is called the coend of $F$. We can use coends to generalize tensor products from modules to functors. Suppose that $F : D \to \text{Vec}$ and $G : D^{\text{op}} \to \text{Vec}$ are functors. Then we define

$$F \otimes_D G = \int^{d \in D} F(d) \otimes G(d).$$ 

A clear exposition of the theory of coends can be found in [Rie14]. Let $D$ a category enriched over $\text{Vec}$. Suppose that we have a functor $D : D^{\text{op}} \to X$. Then we get a functor

$$X \to [D, \text{Vec}]$$

$$X \mapsto X(D(-), X)$$

This functor has a left adjoint given by

$$[D, \text{Vec}] \to X$$

$$V \mapsto V \otimes_D D = \int^d V_d \otimes D^d$$
The following computation demonstrates why these functors are adjoint:

\[ X(V \otimes D, X) = X \left( \int_{d}^{X} V_d \otimes D^d, X \right) \]
\[ = \int_{d}^{X} X(V_d \otimes D^d, X) \]
\[ = \int_{d}^{X} \text{hom}(V_d, X(D^d, X)) \]
\[ = [D, \text{Vec}](V, X(D(-), X)) \]

**Definition 25.** We call \( X \in X \) a **compact** object if \( X(X, -) \) commutes with filtered colimits.

**Proposition 26.** Assume that \( D \) is fully faithful and each \( D(d) \) is projective and compact. Then \( [D, \text{Vec}] \rightarrow X \) is fully faithful.

**Proof.** We need to prove that the unit

\[ V \rightarrow X(D(-), V \otimes D) \]

is an isomorphism. It suffices to prove this pointwise, so we need to prove that the linear map

\[ V(d) \rightarrow X(D(d), V \otimes D) \]

is an isomorphism. Since \( D(d) \) is projective and compact, it follows that \( X(D(d), -) \) commutes with all colimits. Therefore

\[ X(D(d), \int_{x}^{X} V(x) \otimes D(x)) = \int_{x}^{X} V(x) \otimes X(D(d), D(x)) \]
\[ = \int_{x}^{X} V(x) \otimes D(x, d) \]
\[ = V(d) \]

The second equality is true because \( D \) is fully faithful.

**Proposition 27.** In addition to the hypotheses of proposition 26, assume that every \( X \in X \) admits an epimorphism \( \bigoplus_{i} D(d_i) \rightarrow X \) for some family \( \{d_i\} \). Then \( [D, \text{Vec}] \rightarrow X \) is essentially surjective.

**Proof.** By assumption, it follows that for every \( X \in X \), the counit

\[ X(D(-), X) \otimes_D D \rightarrow X \]
is an epimorphism. Then we have an exact sequence

$$0 \to K \to X(D(-), X) \otimes_D D \to X \to 0$$

This gives us an exact sequence

$$X(D(-), K) \otimes_D D \to X(D(-), X) \otimes_D D \to X \to 0$$

Since \(- \otimes_D D\) is fully faithful, we can write the first map as \(f \otimes_D D\) for some map \(f : X(D(-), K) \to X(D(-), X)\). Since \(- \otimes_D D\) is right exact, it follows that \(X = \operatorname{coker} f \otimes_D D\). This proves essential surjectivity.

**Proof of theorem 24.** Let \(D^{\text{op}}\) be a full subcategory of \(X\) whose objects are compact, projective and generate \(X\). Let \(D : D^{\text{op}} \to X\) be the embedding. By proposition, 26, the functor \(- \otimes_D D : [D, \text{Vec}] \to X\) if fully faithful. By Proposition 27, the functor is essentially surjective.

**Definition 28.** If \(X\) is an abelian category with enough compact projectives, define \(M(X)\) to be the opposite of the full subcategory with objects the indecomposable compact projectives. We call \(M(X)\) the **minimal model** for \(X\). By theorem 24, the functor category \([M(X), \text{Vec}]\) is equivalent to \(X\).

### 3.2 Modules over Tensor Algebras

In this section, we work inside a fixed semi-simple tensor category \(C\). We use Morita theory to study the category of modules over an algebra internal to \(C\). Choose a distinguished simple object \(X \in C\). Define

$$T = \bigoplus_{n \geq 0} X^\otimes n$$

This is the tensor algebra generated by \(X\). Define \(\text{Rep}(T)\) to be the category of right modules over \(T\) internal to \(C\). The forgetful functor \(F : \text{Rep}(T) \to C\) has left adjoint \(L : C \to \text{Rep}(T)\) defined by \(V \mapsto V \otimes T\). Since the right adjoint \(F\) is exact, it follows that \(L\) preserves projectives. Define

$$T^+ = \bigoplus_{n \geq 1} X^\otimes n$$

**Lemma 29.** If \(V \in C\) is irreducible, then \(V \otimes T\) is an indecomposable projective in \(\text{Rep}(T)\).
Proof. Since $V \otimes T = L(V)$, the module is projective. Suppose that $V \otimes T = A \oplus B$ as $T$-modules. When we tensor with $T/T^+$, we get

$$V = A/AT^+ \oplus B/BT^+$$

in $C$. Since $V$ is irreducible in $C$, we can assume without loss of generality that $A/AT^+ = 0$. Suppose that $A \neq 0$. Choose $0 \neq Y \subseteq A \subseteq V \otimes T$ irreducible in $C$. This implies that

$$Y \subseteq \bigoplus_{n=0}^{N} V \otimes X^{\otimes n}$$

for some large $N$. Since $A = A(T^+)^{N+1}$, it follows that

$$Y \subseteq A(T^+)^{N+1} \subseteq \bigoplus_{n \geq N+1} V \otimes X^{\otimes n}.$$

This implies that $Y = 0$, which is a contradiction. Therefore we must have $A = 0$. \qed

**Proposition 30.** Let $G$ be the fusion graph for $X$ considered as a category where the objects are vertices and the morphisms are paths. Then $\text{Rep}(T)$ is Morita equivalent to $[G, \text{Vec}]$.

Proof. The indecomposable compact projectives $\lambda \otimes T$, where $\lambda$ is an irreducible in $C$, generate $\text{Rep}(T)$. Using the adjunction $(L, F) : \text{Rep}(T) \rightarrow C$, we have

$$\text{hom}_T(\mu \otimes T, \lambda \otimes T) = C(\mu, \lambda \otimes T).$$

The right hand side has a basis consisting of vectors of the form

$$\lambda \quad X \quad X \quad X$$

$$\mu$$

which is exactly a path in the fusion graph for $X$ from $\lambda$ to $\mu$. Post composing with the
corresponding morphism in $\text{hom}_T(\mu \otimes T, \lambda \otimes T)$ is the map

This implies that composition of basis vectors is exactly concatenation of paths in the fusion graph for $X$. This completes the proof. \qed

**Example 31.** Let $C = \mathcal{H}$, which was defined in Example 21, and let $X = \Box$. The fusion graph for $X$ has objects partitions and the edges $G(\lambda, \mu)$ are the standard skew tableaux of shape $\mu \setminus \lambda$.

### 3.3 Modules over the quantum symmetric algebra

In this section, we work inside the category $\mathcal{H}$ defined in Example 21. Define $T = \bigoplus_{n \geq 0} \Box^\otimes n$. Consider the submodule $I$ of $T$ spanned by all maps
where $\lambda$ is a partition with two or more rows. The grading on the Grothendieck ring implies that $I$ is a 2-sided ideal in $T$, so we can form the quotient algebra $S = T/I$. We have

$$S = \emptyset \oplus \cdots \oplus \cdots \oplus \cdots \oplus \cdots$$

Define $\text{Rep}(S)$ to be category of right modules over $S$ internal to the category $\mathcal{H}$. Just like the tensor algebra, every projective $S$-module is free and the indecomposable projectives are of the form $\lambda \otimes S$ where $\lambda$ is a partition. Define $F$ to be the fusion graph for $\emptyset$ inside $\mathcal{H}$ interpreted as a category. Define $M$ to be the category whose objects are partitions and whose morphisms are defined by

$$M(\lambda, \mu) = \text{hom}_S(\mu \otimes S, \lambda \otimes S).$$

Then we have the functor $Q = - \otimes_T S : F \to M$. By definition, this functor is the identity on objects. Since all the projectives involved are free, it follows that $Q$ is full. We can describe $Q$ more concretely as follows. Each hom space in $F$ is a skew representation of some Iwahori-Hecke algebra. We have:

**Lemma 32.** On morphisms, $Q$ projects onto the Hecke algebra invariants.

*Proof.* Recall that given a vector $f \in F(\lambda, \mu)$, post composition by the induced map $\text{hom}_T(\mu \otimes T, \lambda \otimes T)$ is given by

More precisely, the map $f : \mu \to \lambda \otimes X^{\otimes n}$ induces a map $\mu \otimes T \to \lambda \otimes T$ defined by

$g : \mu \otimes T \xrightarrow{f \otimes 1} \lambda \otimes X^{\otimes n} \otimes T \xrightarrow{1 \otimes m} \lambda \otimes T$

where $m$ is the multiplication map. The diagram depicts post composing a map $\nu \to \mu \otimes T$
with $g$. By Yoneda’s lemma, this determines $g$. If we tensor along the projection $p : T \to S$ we have

\[
\begin{align*}
\mu & \quad \lambda \\
\begin{array}{c}
p \\
\nu
\end{array} & \quad \begin{array}{c}
f \\
m \\
\mu
\end{array} & \quad \begin{array}{c}
m \\
p \\
\mu \nu
\end{array}
\end{align*}
\]

The second equality is true because $p$ is an algebra homomorphism, so it commutes with multiplication. \hfill \Box

**Proposition 33.** Suppose that $\lambda \subseteq \mu$ are partitions. Then $\mathcal{H}(\mu, \lambda \otimes \mathbb{D}^\otimes_n)$ has Hecke algebra invariants if and only if $\mu \setminus \lambda$ is a horizontal strip. In this case, the invariants are 1-dimensional and any skew tableaux projects onto a nonzero invariant.

**Proof.** The invariants in $\mathcal{H}(\mu, \lambda \otimes \mathbb{D}^\otimes_n)$ are the same as maps

\[
\mu \to \lambda \otimes \mathbb{D}^\otimes_n
\]

By Pieri’s rule, $\mathcal{H}(\mu, \lambda \otimes \mathbb{D}^\otimes_n)$ has invariants if and only if $\mu \setminus \lambda$ is a horizontal strip. Suppose that $\mu \setminus \lambda$ is a horizontal strip and $P$ is a skew tableaux of shape $\mu \setminus \lambda$. Then from the semi-normal form, we know that $P$ generates $\mathcal{H}(\mu, \lambda \otimes \mathbb{D}^\otimes_n)$. This implies that $\mathcal{H}(\mu, \lambda \otimes \mathbb{D}^\otimes_n)$ has a 1-dimensional space of invariants and $P$ projects onto a nonzero invariant. \hfill \Box

**Proof of Theorem 23.** The minimal model for $S$ is $M$. From Lemma 32, $Q : F \to M$ is a full functor which is projection onto the Hecke algebra invariants. From Proposition 33, we have

\[
M(\mu, \lambda) = F(\mu, \lambda)^H_n = \mathcal{H}(\mu, \lambda \otimes \mathbb{D}^\otimes_n)^H_n = \mathbf{HS}(\mu, \lambda).
\]

\hfill \Box
CHAPTER 4

A Sufficient Condition for the Braid Group to Surject onto Endomorphism Algebras

Let \( \mathcal{C} \) be a semi-simple braided tensor category defined over a characteristic zero field \( k \). Choose a distinguished object \( X \in \mathcal{C} \). One of the central problems in quantum algebra is deciding if the map \( k[B_n] \rightarrow \text{End}(X^\otimes n) \) is surjective. In [LZ06], Zhang and Lehrer define strongly multiplicity free representations, which gives a sufficient condition in the case when \( \mathcal{C} \) is finite dimensional representations of a Lie algebra or quantum group. Moreover, they classify all strongly multiplicity free representations. In this chapter, we give a new condition which implies that each map \( k[B_n] \rightarrow \text{End}(X^\otimes n) \) is surjective.

4.1 The Affine Braid Group

Definition 34. Let \( \mathcal{C} \) be a semi-simple braided tensor category and \( X \in \mathcal{C} \) a distinguished object. Consider the functor \( T^n_X : \mathcal{C} \rightarrow \mathcal{C} \) defined by \( a \mapsto a \otimes X^\otimes n \). Let \( \sigma_1, \ldots, \sigma_{n-1} \) be the standard generators of the braid group \( B_n \). Then we have a homomorphism

\[
AB_n = \langle \sigma_1^2, \sigma_2, \ldots, \sigma_n \rangle \rightarrow \text{End}(T^n_X)
\]

The braid \( \sigma_1 \) does not act because it has domain \( a \otimes X \) and codomain \( X \otimes a \). We call \( AB_n \) the affine braid group.

Geometrically, \( AB_n \) is like \( B_n \) but the braids are allowed to wrap around a pole on the
More precisely, $AB_n$ is the fundamental group of configurations of $n$ points in $\mathbb{C}\setminus\{0\}$.

Suppose that $\mathcal{C}$ is a braided tensor category and $\lambda \otimes X$ is multiplicity free. Since the double braid must preserve isotypic components, the trivalent vertices are eigenvectors for the double braid. This allows us to define $\theta_\mu / \theta_\lambda \theta_X$ from section 1.6 in a category which may not have duals.

**Definition 35.** Suppose that $\mathcal{C}$ is a braided tensor category. We call $X \in \mathcal{C}$ weakly multiplicity free if for each simple object $\lambda \in \mathcal{C}$, the object $\lambda \otimes X$ is multiplicity free and $\theta_\mu \neq \theta_\nu$ for distinct edges $\lambda \to \mu$ and $\lambda \to \nu$ in the fusion graph of $X$. This definition appears in [LZ06].

**Lemma 36.** Suppose that $X$ is weakly multiplicity free. Then the image of $k[AB_n] \to \text{End}(\lambda \otimes X^{\otimes n})$ contains every diagonal matrix with respect to our chosen trivalent vertices.

**Proof.** Fix a weakly multiplicity free object $X \in \mathcal{C}$ and choose a set of trivalent vertices in $\mathcal{C}$. The operator $\sigma_1^2$ acts on

![Diagram]

via the scalar $c_{\lambda \to \mu} = \theta_\mu / \theta_\lambda \theta_X$. Define

$$P^X_{\lambda \to \mu} = \prod_{\lambda \to \nu \neq \mu} \sigma_1^2 - \frac{c_{\lambda \to \nu}}{c_{\lambda \to \mu} - c_{\lambda \to \nu}} \in k[AB_1]$$

This operator is the projection onto $\mu$ inside $\lambda \otimes X$. It is well-defined because $X$ is weakly
multiplicity free. Since $\sigma_1^2$ is natural in the leftmost strand, we have

It follows that

is a diagonal rank 1 projection living in the affine braid group with eigenvector

This completes the proof.
4.2 The Sufficient Condition

**Definition 37.** Let $C$ be a semi-simple tensor category and fix an object $X \in C$. We say that the fusion graph of $X$ is **discretely simply connected** if for any simple objects $\lambda, \mu \in C$ and any paths $P, Q$ from $\lambda$ to $\mu$, we can transform $P$ to $Q$ using a sequence of moves of the form:

\[
\lambda \to \cdots \to \nu_{i-1} \to \nu_i \to \nu_{i+1} \to \cdots \to \mu \quad \leftrightarrow \quad \lambda \to \cdots \to \nu_{i-1} \to \chi \to \nu_{i+1} \to \cdots \to \mu
\]

This is a combinatorial condition that we can check using the fusion ring of $C$. It is a fun combinatorial exercise to check that the fusion graph of $\square$ in the category of polynomial $\text{GL}(\infty)$-representations is discretely simply connected.

**Theorem 38.** Let $C$ be a braided tensor category and $X \in C$ a weakly multiplicity free object. Suppose the fusion graph of $X$ is discretely simply connected and for each simple object $\lambda$, the map $k[AB_2] \to \text{End}(\lambda \otimes X^{\otimes 2})$ is surjective. Then for each simple object $\mu$ and all $n$, the map $k[AB_n] \to \text{End}(\mu \otimes X^{\otimes n})$ is surjective.

**Proof.** Since the fusion graph for $X$ is discretely simply connected, we can decompose an arbitrary matrix unit into a product of $E_{PQ}$'s where $P$ and $Q$ differ at a single vertex. Therefore, to prove that $k[AB_n] \to \text{End}(\mu \otimes X^{\otimes n})$ is surjective, we need to prove that each matrix unit $E_{PQ}$, where $P$ and $Q$ differ at a single vertex, is in the image. Since each map $k[AB_2] \to \text{End}(\lambda \otimes X^{\otimes 2})$ is surjective and the affine braid group action is natural in the first strand, the image of $k[AB_n] \to \text{End}(\mu \otimes X^{\otimes n})$ contains a term with $E_{PQ}$ as a summand. By Lemma 36, the image contains $E_{PQ}$ after we left and right multiply by the correct diagonal matrices.

**Lemma 39.** Let $X$ be the category of polynomial type 1 $U_a(\text{gl}(\infty))$-representations defined in Chapter 1 and $X = \square$. If $\lambda$ is a partition, then $k[AB_2] \to \text{End}(\lambda \otimes X^{\otimes 2})$ is surjective.

**Proof.** Since $X$ is weakly multiplicity free, by Lemma 36, the image contains all the irreducible projections. Therefore, to prove that $k[AB_2] \to \text{End}(\lambda \otimes X^{\otimes 2})$ is surjective, we need to prove that $k[AB_2]$ acts irreducibly on each multiplicity space $X(\mu, \lambda \otimes X^{\otimes 2})$. In $X$, the multiplicity space $X(\mu, \lambda \otimes X^{\otimes 2})$ has dimension $\leq 2$. If the dimension is 1, there is nothing to prove. Suppose that $\dim X(\mu, \lambda \otimes X^{\otimes 2}) = 2$. Since $\sigma_1^2$ acts diagonally with distinct eigenvalues on the trivalent vertex basis and $\sigma_2$ acts via Young’s semi-normal form which has no zero entries, surjectivity follows.

**Example 40.** Let $X$ be the category of polynomial type 1 $U_a(\text{gl}(\infty))$-representations defined in Chapter 1. Let $X = \square$ be the first fundamental representation. In [LZ06], Lehrer and
Zhang prove that $X$ is weakly multiplicity free. The surjectivity of $A B_2 \rightarrow \text{End}(\lambda \otimes X^\otimes 2)$ was proved in Lemma 39. Let $S, T$ be standard tableaux of shape $\lambda$. Then we can transform $S$ to $T$ by repeatedly swapping entries that are not in the same row or column. It follows that the fusion graph of $X$ is discretely simply connected. Therefore, by Theorem 38, the affine braid group acts irreducibly on the skew partition representations. This result was first proved by Ram in [Ram03].
Let $C$ be a category and $\text{Vec}$ the category of vector spaces over a field $k$ with arbitrary characteristic. Write $\text{Rep}(C)$ for the category of functors $C \to \text{Vec}$. Such functors are called \textit{representations} of $C$. Let $T$ be the category whose objects are rooted trees and morphisms are order embeddings preserving the root. We define this category more precisely in section 5.3. In this chapter we prove

\textbf{Theorem 41.} \textit{Finitely generated $T$-representations are Noetherian.}

Theorem 41 is proved using Gröbner categories, first defined by Richter in [Ric86], and further developed by Sam and Snowden in [SS17]. Gröbner categories reduce Noetherianity questions to combinatorial questions. In all examples that have been done so far, the combinatorial questions reduce to Higman’s Lemma, or some variant. For the category $T$, the combinatorial question reduces to Kruskal’s tree Theorem.

\section{Motivation and previous work}

Theorem 41 is a generalization of Theorem 42, which was proved independently by Church, Ellenberg and Farb in [CEF15] and by Snowden in [Sno13]. Indeed, the full subcategory of $T$ with objects height one trees if $\text{FI}$.

\textbf{Theorem 42.} \textit{Let $\text{FI}$ be the category of finite sets with injections. Then finitely generated $\text{FI}$-representations over a field of characteristic 0 are Noetherian.}

Theorem 42 has the following Corollary, due to Church, Ellenberg and Farb in [CEF15]:

\textbf{Corollary 43.} \textit{Let $M$ be a manifold and $S$ a finite set. Then $S \mapsto C_S(M) = \{\text{injections } S \to M\}$ is a functor from $\text{FI}^{\text{op}}$ into the category of manifolds, and $S \mapsto H^d(C_S(M), \mathbb{Q})$ is a finitely generated $\text{FI}$-representation.}
We hope that Corollary 43 convinces the reader that Theorems 41 and 42 are interesting. Motivated by Theorem 42, Sam and Snowden developed the theory of Gröbner categories in [SS17]. They proved

**Theorem 44.** Let $C$ be quasi-Gröbner category. Then every finitely generated $C$-representation is Noetherian.

Sam and Snowden also proved that the categories $\mathbf{FI}_d, \mathbf{FS}_{\text{op}}, \mathbf{VA}, \mathbf{FI}_G, \mathbf{FS}_{G}^\text{op}$ are quasi-Gröbner. In all of these examples, the objects are parameterized by the natural numbers. The category $\mathbf{T}$ may be the first known example of a quasi-Gröbner category whose objects do not have a natural bijection with $\mathbb{N}^p$.

### 5.2 Open problems

As far as the author is aware, the following questions are open:

1. Are there any interesting spaces which are acted upon by tree automorphism groups? If we could find non trivial functors from $\mathbf{T}^\text{op}$ into the category of spaces, then Theorem 41 might imply results like Corollary 43.

2. If $V$ is a finitely generated $\mathbf{T}$-representation, what can one say about the function $T \mapsto \dim V_T$? If $C$ is a quasi-Gröbner category, then it is reasonable to expect that the Hilbert series of finitely generated $C$-representations will be nice. For example, finitely generated $\mathbf{FI}$-representations have rational Hilbert series.

3. Kruskal’s tree Theorem is an important part of the graph minor Theorem. The category $\mathbf{T}$ is quasi-Gröbner because of Kruskal’s tree Theorem. Is there any category that is quasi-Gröbner because of the graph minor Theorem?

### 5.3 Rooted Trees

In this section, we explain the terms and notation used throughout the chapter. A **tree** is a connected finite graph with no loops. A **rooted tree** is a tree equipped with a root vertex. In a rooted tree, we orient every edge towards the root vertex. When drawing rooted trees,
the root vertex is at the bottom. Here is an example:

If \( v \) is a vertex, write \( \text{in}(v) \) for the set of incoming edges. When we draw a picture of a rooted tree, we implicitly put an ordering on \( \text{in}(v) \) for each vertex \( v \). A **planar rooted tree** is a rooted tree equipped with a total ordering on \( \text{in}(v) \) for each vertex \( v \). Given a rooted tree \( T \) we build a partially ordered set as follows: The elements are vertices and given vertices \( v, w \) we say that \( v \leq w \) if there is a downward path from \( v \) to \( w \). We call this order the **tree order** on the vertices of \( T \). The root is larger than all other vertices in the tree order. Let \( T \) be a planar rooted tree. We totally order the vertices using a clockwise depth-first tree walk. This total ordering is called the **depth-first ordering** on the vertices and is denoted by \( \prec \). A map of partially ordered sets \( f : P \to Q \) is called an **order embedding** when \( f(x) \leq f(y) \) if and only if \( x \leq y \). When we say order embedding, we mean with respect to the tree order.

We define the following categories:

\[
\begin{align*}
\text{FT} &= \left\{ \text{Objects are rooted trees and morphisms are order embeddings} \right\} \\
\text{FPT} &= \left\{ \text{Objects are planar rooted trees and morphisms are order embeddings which also preserving the depth-first ordering on vertices} \right\} \\
\text{T} &= \left\{ \text{Objects are rooted trees and morphisms are order embeddings preserving the root} \right\} \\
\text{PT} &= \left\{ \text{Objects are planar rooted trees and morphisms are order embeddings that preserve the root and the depth-first ordering on vertices} \right\}
\end{align*}
\]

The categories \( \text{T} \) and \( \text{PT} \) are our main focus, but for many of the proofs, it is useful to work in \( \text{FT} \) and \( \text{FPT} \). Since the morphism are order embeddings, they are injective on vertices. We can now state our main theorem, from which Theorem 41 follows. First, let us recall
the definition of a Gröbner category from [SS17].

**Definition 45.** A quasi-order is a binary relation that is reflexive and transitive. A well-quasi-ordering is a quasi-ordering such that any infinite sequence of elements $x_0, x_1, x_2, \ldots$ contains an increasing pair $x_i \leq x_j$ with $i < j$.

Let $C$ be a small directed category. Write $C_x = \bigcup_y \text{Mor}_C(x, y)$. If $f : x \to y$ and $g : x \to z$ are elements of $C_x$ then we write $f \leq g$ if there is a commutative triangle

$$
\begin{array}{ccc}
  x & \xrightarrow{f} & y \\
    & \searrow{g} & \\
    &      & z
\end{array}
$$

We call this quasi-order on $C_x$ the **divisibility order**. It is intrinsic to $C$. An admissible order on $C_x$ is a well-order $\preccurlyeq$ such that if $f \preccurlyeq f'$ then $gf \preccurlyeq g'f'$ whenever this makes sense. Admissible orders are not intrinsic to $C$: they are extra structure.

**Definition 46.** We call $C$ Gröbner if each divisibility order $C_x$ is a well-quasi-order and each $C_x$ admits an admissible order.

**Definition 47.** Let $i : C' \to C$ be a functor. We say that $i$ has property (F) if for each principal projective $P_x = \mathbb{C}C(x, -)$ in $\text{Rep}(C)$, the $C'$-representation $i^* P_x$ is finitely generated.

**Definition 48.** A category $C$ is quasi-Gröbner if there is a Gröbner category $C'$ and an essentially surjective functor $C' \to C$ satisfying property (F).

**Theorem 49.** The category $\mathbb{P}T$ is Gröbner and the forgetful functor $\mathbb{P}T \to T$ is essentially surjective and has property (F).

Theorem 49 implies that $T$ is quasi-Gröbner. We refer the reader to [SS17] where the theory of Gröbner categories is developed.

### 5.4 A relative version of Kruskal’s tree Theorem

We define a sequence of trees $B_1, B_2, B_3, B_4, \ldots$ as follows: $B_n$ is the graph with vertex set $\{*, 1, \ldots, n\}$ and edges $(i, *)$. Diagrammatically, we have

```
  *  \  1 \  2 \  3 \  4 \  ...
```

These planar rooted trees form building blocks in the category $\mathbb{F}PT$. 

46
Lemma 50. Let $T$ be a planar rooted tree. Let $v$ be a vertex of $T$. Let $T_v$ be the sub tree of $T$ which contains everything above and including $v$. Let $T^v$ be the sub tree of $T$ obtained by removing everything in $T_v$ strictly above $v$. Then we have the following pushout square in $\text{FPT}$:

$$
\begin{array}{ccc}
T_v & \longrightarrow & T \\
\uparrow & & \uparrow \\
v & \longrightarrow & T^v
\end{array}
$$

Proof. To define a morphism $T \to U$, we need to send edges in $T$ to paths in $U$ so that domains and codomains are preserved. Since every edge in $T$ is contained in either $T_v$ or $T^v$, the lemma follows. \hfill \square

Example 51. Here is an example of such a pushout square:

Lemma 52. Assume that $T$ is a planar rooted tree and $v_1,\ldots,v_n$ are the vertices with distance 1 from the root. Then $T$ is a colimit of the following diagram (that we have only drawn for $n = 3$):

$$
\begin{array}{ccc}
T_{v_1} & \longrightarrow & T_{v_2} & \longrightarrow & T_{v_3} \\
\uparrow & & \uparrow & & \uparrow \\
v_1 & \longrightarrow & v_2 & \longrightarrow & v_3 \\
\downarrow & & \downarrow & & \downarrow \\
B_3 & \longrightarrow & & \longrightarrow &
\end{array}
$$

Proof. This follows by repeated application of Lemma 50. \hfill \square

Lemma 53. We have a natural isomorphism

$$
\text{Mor}_{\text{FPT}}(B_n, T) = \begin{cases} 
\text{distinct vertices } v, v_1,\ldots,v_n \in T \text{ such that } \\
v_1 \preceq v \text{ in the tree order, the } v_i \text{ are pairwise incomparable in the tree order and } v_1 \not\preceq v_2 \preceq \cdots \preceq v_n \text{ in the depth-first order}
\end{cases}
$$
Proof. To specify a map out of $B_n$ inside $\mathbf{FPT}$, we need to specify the images of the root and leaves subject to planar ordering.

Let $T$ be a planar rooted tree. Define $\mathbf{PT}_T$ to be the set of morphisms in $\mathbf{PT}$ with domain $T$. If $f, g \in \mathbf{PT}_T$, we define $f \leq g$ if there is a commutative diagram

$$
\begin{array}{c}
T \\ \downarrow^g \\
\rightarrow \\
V
\end{array}
\begin{array}{c}
\rightarrow \\
U
\end{array}
\begin{array}{c}
\rightarrow \\
\downarrow^f \\
\rightarrow \\
V
\end{array}
$$

in the category $\mathbf{PT}$. Equivalently, $f \leq g$ if there is a morphism $h$ such that $g = hf$. This is called the divisibility quasi-order on $\mathbf{PT}_T$. Now we can state the relative version of Kruskal’s tree Theorem:

**Theorem 54.** The quasi-order on $\mathbf{PT}_T$ is a well-quasi-order.

The $T = \bullet$ case is very similar to Kruskal’s tree Theorem. Indeed, Lemma 55 is proved by Draisma in [Dra14]. We include a proof to establish notation and demonstrate the main proof technique in the easiest case.

**Lemma 55.** Theorem 54 is true when $T = \bullet$.

Proof. We use the Nash–Williams theory of good/bad sequences that is explained in [Die10, Chapter 12]. We call a sequence $x_0, x_1, x_2, \ldots$ good if there exist indices $i < j$ such that $x_i \leq x_j$. Otherwise, the sequence is called bad. Suppose that $\mathbf{PT}_\bullet$ is not well-quasi-ordered. Given $n \in \mathbb{N}$, assume inductively that we have chosen a sequence $T_0, \ldots, T_{n-1}$ of planar rooted trees such that some bad sequence of planar rooted trees starts with $T_0, \ldots, T_{n-1}$. Choose $T_n$ with a minimal number of vertices such that some bad sequence starts $T_0, T_1, \ldots, T_n$. Then $(T_n)_{n \in \mathbb{N}}$ is a bad sequence. We call $(T_n)$ a minimal bad sequence. Let $v_1, \ldots, v_d$ be the vertices in $T_n$ whose distance from the root is 1, ordered with respect to the depth-first ordering. Let $A_n = T_{n,v_1}T_{n,v_2} \ldots T_{n,v_d}$. If we think of each sequence $A_n$ as a set, we can define $A = \cup_n A_n$. We claim that $A$ is well-quasi-ordered. Let $(U_k)$ be a sequence in $A$. Then $U_k \in A_{n(k)}$, so we have a morphism $U_k \rightarrow T_{n_k}$ in $\mathbf{FPT}$. This morphism does not preserve the root, but we can modify what the morphism does on the root vertex in the following way:

This allows us to convert $U_k \rightarrow T_{n_k}$ into a morphism which witnesses $U_k \leq T_{n_k}$. Choose $p$
so that \( n(p) \) is the smallest element of \( \{ n(k) \} \). Then we have the following sequence

\[
T_0, \ldots, T_{n(p) - 1}, U_p, U_{p+1}, \ldots
\]

By the minimality of \( (T_n) \), it must have a good pair. If \( T_i \leq U_j \) then we have \( T_i \leq T_{n(j)} \). This is a contradiction because \( i < n(p) \leq n(j) \). Therefore there must be a good pair in \( (U_k) \). Since our choice of sequence in \( A \) was arbitrary, it follows that \( A \) is well-quasi-ordered.

Consider the following sequence of words in \( A \):

\[
A_0, A_1, A_2, \ldots
\]

By Higman’s Lemma, we must have \( A_i \leq A_j \) for some \( i < j \). What this means is that there is an order preserving injection \( \phi : A_i \rightarrow A_j \) such that \( U \leq \phi(U) \) for each \( U \in A_i \). This gives us \( T_i \leq T_j \) which is a contradiction.

**Lemma 56.** Theorem 54 is true when \( T = B_n \).

**Proof.** The proof is by induction on \( n \). The base case is \( n = 1 \). Elements in \( \text{PT}_{B_1} \) are planar rooted trees with a distinguished non-root vertex and \( T \leq U \) if there is a morphism \( T \rightarrow U \) preserving the root and the distinguished non-root vertex. Choose a minimal bad sequence \( (T_n) \) in \( \text{PT}_{B_1} \). Define \( A_n \) as in Lemma 55. We can break the sequence \( A_n \) up as \( L_n U_n R_n \) where \( U_n \) is the tree containing the distinguished vertex, \( L_n \) is the sequence of trees coming before \( U_n \) and \( R_n \) is the sequence of trees coming after \( U_n \) in the depth first ordering. There are two cases we need to consider:

1. Suppose that for an infinite subsequence \( (U_{n_k}) \) of \( (U_n) \), the distinguished vertex in \( T_{n_k} \) is the root of \( U_{n_k} \). Consider the following sequence

\[
(L_{n_1}, U_{n_1}, R_{n_1}), (L_{n_2}, U_{n_2}, R_{n_2}), \ldots
\]

A product of well-quasi-orders is a well quasi-order. By Lemma 55, there must be a good pair \( (L_{n_1}, U_{n_1}, R_{n_1}) \leq (L_{n_j}, U_{n_j}, R_{n_j}) \) which gives us \( T_{n_1} \leq T_{n_j} \) in \( \text{PT}_{B_1} \). This is a contradiction.

2. Suppose that for an infinite subsequence \( (U_{n_k}) \) of \( (U_n) \), the distinguished vertex in \( T_{n_k} \) is not the root of \( U_{n_k} \). The obvious morphism \( U_{n_k} \rightarrow T_{n_k} \) does not preserve roots, but we can use the same trick as in Lemma 55 to get \( U_{n_k} \leq T_{n_k} \) in \( \text{PT}_{B_1} \). Since we started with a minimal bad sequence, \( \{U_{n_k}\} \) must be well-quasi-ordered, therefore the sequence

\[
(L_{n_1}, U_{n_1}, R_{n_1}), (L_{n_2}, U_{n_2}, R_{n_2}), \ldots
\]
must have a good pair \((L_{n_i}, U_{n_i}, R_{n_i}) \leq (L_{n_j}, U_{n_j}, R_{n_j})\) which gives us \(T_{n_i} \leq T_{n_j}\) in \(PT_{B_1}\).

This is a contradiction.

One of these two cases must occur. Therefore we have proved that \(PT_{B_1}\) is well-quasi-ordered. Now assume that \(PT_{B_i}\) is well-quasi-ordered for \(i < n\). We prove that \(PT_{B_n}\) is well-quasi-ordered. Elements of \(PT_{B_n}\) are planar rooted trees with \(n\) distinguished non–root vertices \(v_1, \ldots, v_n\) that are incomparable in the tree order and ordered in the depth-first order. We have \(T \leq U\) if there is a morphism \(T \rightarrow U\) in \(FPT\) that preserves the root and the distinguished non root vertices. Assume that \((T_n)\) is a minimal bad sequence in \(PT_{B_n}\). As usual, form the sequence \((A_n)\). Define \(\omega(A_n)\) as follows: replace each tree in \(A_n\) with the number of distinguished vertices of \(T_n\) it contains, then delete the zeros. By the pigeonhole principle

\[
\omega(A_1), \omega(A_2), \omega(A_3), \ldots
\]

must contain some sequence \(m_1, \ldots, m_d\) an infinite number of times. Let \((T_{n_k})\) be the corresponding subsequence of \((T_n)\). We must now consider two cases:

1. Suppose \(d = 1\). Write \(A_{n_k} = L_{n_k} U_{n_k} R_{n_k}\) where \(U_{n_k}\) contains all of the distinguished vertices in \(T_{n_k}\). If there is an infinite subsequence where the root of \(U_{n_k}\) is not distinguished, then use a minimal bad sequence argument to get a contradiction. If there is an infinite subsequence where the root of \(U_{n_k}\) is distinguished, then use the induction hypothesis to get a contradiction.

2. If \(d > 1\) then write

\[
A_{n_k} = L_{n_k}^0 U_{n_k}^1 L_{n_k}^1 \ldots U_{n_k}^d L_{n_k}^d
\]

where \(U_{n_k}^i\) has \(m_i\) of the distinguished vertices. Now use the induction hypothesis to get a contradiction.

Proof of Theorem 54. We induct on the number of vertices in \(T\). Lemma 56 is the base case. Choose a non–root vertex \(v\) in \(T\) that has valence \(\geq 2\). Choose a sequence \((\phi_n : T \rightarrow U_n)\) in \(PT_T\). Then we get sequences \(\phi_{n,v} : T_v \rightarrow U_n\phi_n(v)\) and \(\phi_n^v : T^v \rightarrow U_n^\phi_{n,v}(v)\) in \(PT_{T_v}\) and \(PT_{T^v}\) respectively. By induction, there must be a good pair \((\phi_{i,v}, \phi_i^v) \leq (\phi_{j,v}, \phi_j^v)\). This induces \(\phi_i \leq \phi_j\) which completes the proof.
5.5 Proof of Main Theorem

In this section, we prove that $PT$ is a Gröbner category and that the forgetful functor $PT \to T$ has property (F) and is essentially surjective. Theorem 54 says that the divisibility order on $PT_T$ is a well-quasi-order. Therefore, to prove that $PT$ is Gröbner, we need to construct admissible orders on each $PT_T$. Let $T, U$ be planar rooted trees and choose a morphism $\phi : T \to U$ in $PT$. If $e$ is an edge in $T$, label every edge in the path $\phi(e)$ with the distance between target($e$) and root($T$) in $T$. (edges point towards the root). Now we go on a clockwise depth-first tree walk along $U$ (depth-first tree walks are defined in [Sa99, chapter 5]). As we are traveling, record the path as follows:

1. If we travel up an edge marked with an $i$, write $()$.
2. If we travel down an edge marked with an $i$, write $)$
3. If we travel up an unmarked edge, write $(
4. If we travel down an unmarked edge, write $)$. 

The resulting string is called the Catalan word of $\phi$.

Example 57. consider the map:

\[
\begin{align*}
\begin{array}{c}
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\bullet
\end{array}
\end{align*}
\]

\[
\begin{align*}
\begin{array}{c}
\bullet \\
\bullet \\
\bullet \\
\bullet \\
\bullet
\end{array}
\end{align*}
\]

Its Catalan word is

\[
(((()()()())())()())
\]

If $T = \bullet$ then we recover the the standard bijection between planar rooted trees and strings of balanced brackets which is described in [Sa99, chapter 5].

Lemma 58. The mapping $\phi \mapsto$ Catalan word is injective.

Proof. We can reproduce $\phi$ from its Catalan word as follows. The top row of parentheses gives the target. The bottom row of numbers tells us how the domain is mapped in, and also gives the domain since all tree maps are fully faithful. \qed

51
We use Catalan words to equip each set $\mathbf{PT}_T$ with an admissible order. Given a Catalan word, build the tuple $(p,n)$ where $p$ is the top row and $n$ is the second row. We order the alphabets in the following way:

\[
) < ( \\
- < 0 < 1 < 2 < 3 < \ldots
\]

Order words in the parentheses alphabet using the length lexicographic ordering. Order words in \{-,0,1,2,\ldots\} using lexicographic ordering. Given two Catalan words $(p,n),(p',n')$, define $(p,n) < (p',n')$ if $p < p'$ or $p = p'$ and $n < n'$.

**Lemma 59.** Let $f,g : T \to U$ be morphisms in $\mathbf{PT}$ such that $f < g$ with respect to the above Catalan word ordering. Let $h : U \to V$ be a morphism. Then $hf < hg$.

**Proof.** First we interpret $f < g$. When we go on a clockwise depth-first tree walk along $U$, the first time we notice a difference in the edge labeling, the label for $g$ is larger than the label for $f$. Now go on a clockwise depth-first tree walk along $V$ labeled by $hf$ and $hg$. The first difference that we notice is going to be induced by the difference we noticed on our walk along $U$ and the label for $hg$ will be bigger than the label for $hf$ because the labels are mapped from $U$.

This completes the construction of admissible orders on each $\mathbf{PT}_T$. Therefore we have proved that $\mathbf{PT}$ is Gröbner. To conclude the proof of Theorem 49, we need to prove that the forgetful functor $i : \mathbf{PT} \to \mathbf{T}$ is essentially surjective and has property (F). Let $J : \mathbf{PT} \to \mathbf{T}$ be the functor which forgets the plane ordering. Since every rooted tree can be drawn on the plane it follows that $J$ is essentially surjective. Let $U$ be a rooted tree and $V$ a planar rooted tree. Then we have

\[
\mathbf{T}(U,J(V)) = \mathbf{PT}(U_1,V) \sqcup \mathbf{PT}(U_2,V) \sqcup \cdots \sqcup \mathbf{PT}(U_e,V)
\]

where $U_1,\ldots,U_e$ are all the planar representations of $U$. This implies that

\[
J^* P_U = \bigoplus_{i=1}^{e} P_{U_i}
\]

which proves that $J$ has property (F).
